

To keep things organised, create a new directory and enter it to store files using `mkdir` and `cd`

First, create a text file called `my_secrets` and insert some secret message in there.

Insert the key into this directory using the command:

```
openssl rand -base64 16 > key.txt
```

```
File Actions Edit View Help
0es Kali Forums Kali NetHunter Exploit-DB Google Hack
(kali@kali)-[~/ransom]
$ openssl rand -base64 16 > key.txt
```

After the insertion of the key, the ransomware should be ready for execution.

Run the command:

```
python3 ransomware.py
```

After the command is run, multiple dots and other symbols should show up

[illegible]

This is all part of the program.

At the end of text, the ransom message should show up:

```
..+...+.+++++  
writing RSA key  
Your file my_secrets.txt is encrypted. To decrypt it, you need to pay me $1,000 and send key_cipher.txt to me.
```

The ransomware code has worked. To check if the key.txt and my_secrets.txt files are deleted, run ls command in that directory:

```
> PS Biniam Seyoum
(kali㉿kali)-[~/ransom] 6:26 PM
$ ls
data_cipher.txt  key_cipher.txt  private.pem  public.pem  ransomware.py
```
